CS 260: Foundations of Data Science

Prof. Thao Nguyen Fall 2024

Materials by Sara Mathieson

Admin

- Roster should hopefully be finalized by end of week
 - If you are #3 or higher on the waitlist, please find another class (CS260 will be offered again in the Spring!)
- Lab 1 due Tuesday night
- Extra office hours: **3—4pm on Friday** (H110)
- Regular office hours: 10—11:30am on Tuesday (H110)

Note-cards from Tuesday

- Practice problems and group work: many people mentioned these – will try to have every class
- Demos and videos: several people mentioned these – I will try!
- Access to myself and TAs: some people mentioned this – TA hours have been posted

– Friday 11am-1pm hours this week

AAAI-25 Undergraduate Consortium

- February 25-26, 2025
- Mentoring program for undergraduate students interested in a career in AI research
- Application deadline: September 30, 2024

FEBRUARY 25 – MARCH 4, 2025 | PHILADELPHIA, PENNSYLVANIA, USA

Introductions

(if you could be a data scientist for any type of data, what would it be?)

Python Demo

- Matplotlib
- Numpy
- Dictionaries

Outline for today

• Object-oriented programming (OOP) in Python

• Reading in data in Python

• Numerical Python (numpy)

• If time: begin data representation

Outline for today

• Object-oriented programming (OOP) in Python

• Reading in data in Python

• Numerical Python (numpy)

• If time: begin data representation

- Classes allow us to encapsulate common data structures and actions so we don't have to define them over and over again
- Example: say we have two classes: **Point** and **Circle**

- Classes allow us to encapsulate common data structures and actions so we don't have to define them over and over again
- Example: say we have two classes: **Point** and **Circle**
- We can create a new *instance* of a class using the *constructor*

dot = Circle(Point(x,y), r)

- Classes allow us to encapsulate common data structures and actions so we don't have to define them over and over again
- Example: say we have two classes: **Point** and **Circle**
- We can create a new *instance* of a class using the *constructor*

```
dot = Circle(Point(x,y), r)
```

• We can access the instance's data using *methods*

r = dot.get_radius()

- Classes allow us to encapsulate common data structures and actions so we don't have to define them over and over again
- Example: say we have two classes: **Point** and **Circle**
- We can create a new *instance* of a class using the *constructor*

dot = Circle(Point(x,y), r)

• We can access the instance's data using *methods*

r = dot.get_radius()

• We can use/modify class instances using *methods*

dot.move(dx,dy)

Motivation for classes: LOLs

 List-of-lists let us keep track of things that should be "together", but they get cumbersome to modify:

Type of pie

```
>>> pie_lst = [["apple",8], ["cherry",8], ["chocolate",8]]
>>>
>>> pie_lst[2][1] -= 1
>>>
[>>> pie_lst
[>>> pie_lst
[['apple', 8], ['cherry', 8], ['chocolate', 7]]
```

Motivation for classes: encapsulation and abstraction

 Neither encapsulated (data for one student is spread over multiple objects), nor abstract

```
name_lst = ["Kendre", "Rohan", "Ayaka", "Maleyah"]
year_lst = [2020, 2021, 2020, 2021]
name = name_lst[0]
year = year_lst[0]
```

Motivation for classes: encapsulation and abstraction

• Neither encapsulated (data for one student is spread over multiple objects), nor abstract

 Encapsulated (student is represented as one thing, a list), but not abstract

```
kendre = ["Kendre", 2020, ["cs35","act1","relg43","span1"]]
name = kendre[0]
year = kendre[1]
```

Motivation for classes: encapsulation and abstraction

• Neither encapsulated (data for one student is spread over multiple objects), nor abstract

 Encapsulated (student is represented as one thing, a list), but not abstract

```
kendre = ["Kendre", 2020, ["cs35","act1","relg43","span1"]]
name = kendre[0]
year = kendre[1]
```

• Both abstract and encapsulated

<u>Should be:</u> get_name() get_year()

kendre = Student("Kendre", 2020)
name = kendre.getName()
year = kendre.getYear()

Advantages of encapsulation/abstraction

• Interface (how you interact with something) is consistent even if the internal details change.

1) If you change the engine in your car, you still drive it the same way – don't need to know how the engine works.

In online shopping you have a "Cart", which is an abstract concept and is roughly the same across sites.
 Probably represented as a list underneath but user doesn't need to know.

"Pie" class example

```
class Pie: # class names should be capitalized
   # must use init for the constructor
   def __init__(self, flavor):
        """Constructor for the Pie class."""
       # in the constructor, define the data (i.e. self.data)
       # data are called: attributes or instance variables
       self.flavor = flavor
       self.slices = 8
   def get_slices(self):
        """Return the number of slices left (int)."""
        return self.slices
   def get_flavor(self):
        """Return the flavor of the pie (str)."""
        return self.flavor
```

"Pie" class example

```
def serve(self):
    """If there is at least one slice left, reduce the number of slices."""
    if self.slices > 0:
        print("Here is a slice of %s pie!" % self.flavor)
        self.slices -= 1
    else:
        print("Sorry, there is no more %s pie!" % self.flavor)
def str (self):
    """Return a string representation of a pie."""
    s = "%s pie has %i slices left!" % (self.flavor, self.slices)
    return s
```

"Pie" class example

```
def main():
    pie1 = Pie("apple")
    print(pie1) # __str__ is automatically called when we call print(...)
                                        apple pie has 8 slices left!
    for i in range(12):
                                        Here is a slice of apple pie!
        pie1.serve()
                                        Here is a slice of apple pie!
    print(pie1.get_slices())
                                        Here is a slice of apple pie!
    print(pie1.get_flavor())
                                        Here is a slice of apple pie!
    print(pie1)
                                        Here is a slice of apple pie!
                                        Here is a slice of apple pie!
                                        Here is a slice of apple pie!
    pie2 = Pie("pumpkin")
                                        Here is a slice of apple pie!
    print(pie2)
                                        Sorry, there is no more apple pie!
    pie2.serve()
                                        Sorry, there is no more apple pie!
    print(pie2)
                                        Sorry, there is no more apple pie!
                                        Sorry, there is no more apple pie!
                                        0
                                        apple
                                        apple pie has 0 slices left!
                                        pumpkin pie has 8 slices left!
                                        Here is a slice of pumpkin pie!
                                        pumpkin pie has 7 slices left!
```

TwitterUser class

```
class TwitterUser: # only time camel case is okay!
   # constructor
    def __init__(self, name, curr_following, curr_followers):
        self.name = name
        self.following = curr_following
        self.followers = curr_followers
    def add_follower(self): # always have to use self!
        self.followers += 1
        # TODO we could make this better by creating a list of followers who
        # are themselves instances of TwitterUser
    def follow(self):
        self.following += 1
    def __str__(self):
        # must return a string, not print a string!
        return "name: %s\nnum following: %i\nnum followers: %i" % (self.name, \
            self.following, self.followers)
```

Handout 2

• Find and work with a partner

 <u>Defining the Constructor</u>: builds an instance of the class (self), and initializes all instance variables (self.xxx)

 <u>Defining the Constructor</u>: builds an instance of the class (self), and initializes all instance variables (self.xxx)

 Using the Constructor: assign the new object to a variable, making the "self" placeholder a concrete instance

 <u>Defining Methods</u>: always use "self" as the first argument (placeholder for the instance). Getters are a type of method that return instance variables or

their derivatives.

def getValue(self):
 """Getter for the die's current value."""
 return self.value

def roll(self):
 """Choose a new random value for the die, i.e. roll it."""
 self.value = random.randrange(1,self.sides+1)

 <u>Defining Methods</u>: always use "self" as the first argument (placeholder for the instance). Getters are a type of method that return instance variables or

their derivatives.

def getValue(self):
 """Getter for the die's current value."""
 return self.value

def roll(self):

"""Choose a new random value for the die, i.e. roll it."""
self.value = random.randrange(1,self.sides+1)

<u>Using Methods</u>: instance.method(...), don't use self

 <u>Defining the str method</u>: no print(..) statements! Build and return a single string. (no arguments besides self)

def __str__(self):
 """String representation of the die (with current value)."""
 return "%d-sided die, current value: %d" % (self.sides, self.value)

 <u>Defining the str method</u>: no print(..) statements! Build and return a single string. (no arguments besides self)

def __str__(self):
 """String representation of the die (with current value)."""
 return "%d-sided die, current value: %d" % (self.sides, self.value)

• <u>Using the str method</u>: simply call print(instance)!

Outline for today

• Object-oriented programming (OOP) in Python

• Reading in data in Python

• Numerical Python (numpy)

• If time: begin data representation

```
# open(..) returns a file object (called an TextIOWrapper but think: file)
c_file = open("colleges.txt", 'r') # 'r' for read, 'w' for write
enroll_lst = []
# one way to read a file: loop through each line of the file
                                                           colleges.txt
for line in c_file:
                                                     Amherst 1792
   # split breaks up the line on spaces, it is a method the
                                                     Bates 1792
   tokens = line.split()
                                                     Bowdoin 1806
                                                     BrynMawr 1709
   # extract information from specific tokens
                                                     Colby 1815
   name = tokens[0]
                                                     Davidson 1950
   enroll = int(tokens[1])
                                                     HarveyMudd 735
   enroll lst.append(enroll)
                                                     Haverford 1290
                                                     Middlebury 2526
# always remember to close your files!
                                                     Pomona 1663
c_file.close()
                                                     Reed 1411
                                                     Smith 2600
                                                     Swarthmore 1620
Example of reading in data
                                                     Vassar 2450
                                                     Wellesley 2474
```

Williams 2099

File reading demo

```
import csv
import numpy as np
# 1) read line by line
fb_file = open("data/facebook_users.csv", 'r') # 'r' for read mode
for line in fb_file:
    tokens = line.split(",") # split on comma
    year = int(tokens[0])
    num_users = int(tokens[1])
    print(year, num_users)
fb_file.close()
# 2) csv reader
with open("data/facebook_users.csv", 'r') as fb_file:
    csv_reader = csv.reader(fb_file)
    for line in csv_reader:
        print(line)
# 3) load into numpy array
data = np.loadtxt("data/facebook_users.csv", dtype=int, delimiter=",")
print(data)
```

Outline for today

• Object-oriented programming (OOP) in Python

• Reading in data in Python

• Numerical Python (numpy)

• If time: begin data representation

Numpy

- Numerical Python
- Designed for fast computation on arrays
- Implemented in C underneath
- pip3 install numpy (on the terminal) OR
 python3 –m pip install numpy

Numpy concatenation

np.concatenate((A,B), axis=0)

np.concatenate((A,B), axis=1)

must match along axis 1

Numpy concatenation

np.concatenate((A,C), axis=0)

np.concatenate((A,C), axis=1)

Error: must match along axis 0!

must match along axis 1

Outline for today
